White-Box Cryptography

Ph.D graduation presentation
Brecht Wyseur

March 5, 2009, Heverlee

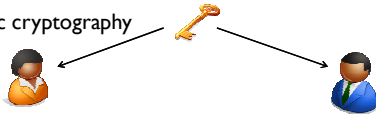

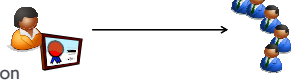

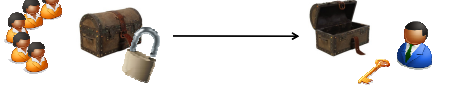

Cryptography: the basic principle

- ▶ **Basic assumption**
 - ▶ Adversary has knowledge of the algorithm (Kerckhoffs 1883 [104])
 - Security of a cryptosystem system relies on the confidentiality of the key

▶ 2

Keys in cryptography

- ▶ **Symmetric cryptography**

- ▶ **Asymmetric cryptography**
 - ▶ Digital signatures
 
 - ▶ Public-key encryption
 

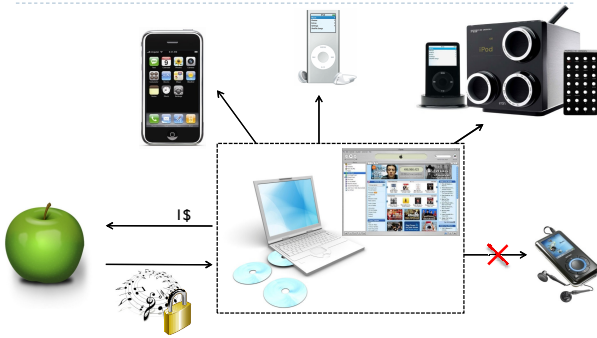

▶ 3

Cryptography is part of our modern life

- ▶ Telecommunication
 
- ▶ Financial
 
- ▶ Transport
 
- ▶ Identification
 
- ▶ Recreational
 
- ▶ ...

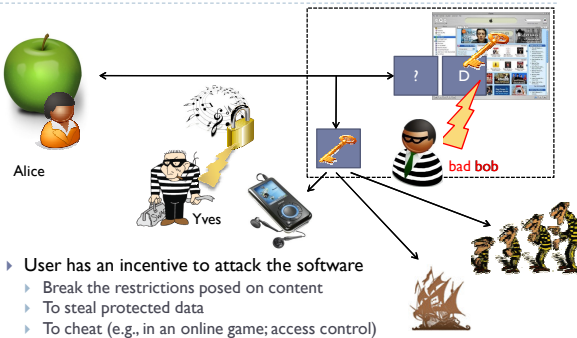

▶ 4

Example: iTunes

▶ 5

Example: iTunes (2)

- ▶ **User has an incentive to attack the software**
 - ▶ Break the restrictions posed on content
 - ▶ To steal protected data
 - ▶ To cheat (e.g., in an online game; access control)

▶ 6

Software Attacks

- ▶ When a user has an incentive to attack
- ▶ Or is subject to malware

White-box attack model

- ▶ Adversary has fully-privileged access to the execution platform
- ▶ Dynamic execution (with instantiated cryptographic keys) can be observed,
- ▶ Internal details of implementations are completely visible and alterable at will.

▶ 7

Software attacks

- ▶ Reverse engineering: attempt to decompile or understand binary code
- ▶ Tools: IDA Pro, OllyDbg, Syser, Objdump, ...

▶ 8

Entropy Attack

(Shamir and Van Someren, 1999, [167])

Computergeheugen:

■ 0-bit
□ 1-bit

- ▶ Keys need to be chosen at random from a (uniform) distribution → high entropy.
- ▶ Code typically contains structure → low entropy

▶ 9

Key Whitening Attack

(Kerins and Kursawe, 2006 [104])

- ▶ Implementation attack on ciphers that deploy a key-whitening (e.g., AES)

```

- ▶ Strategy: identify and overwrite S-box definition in binary:
 $S \rightarrow 0$, then
 $y = 0 + k$

▶ 10

Digital Rights Management (DRM)

- ▶ Digital management of rights (/restrictions)
 - ▶ Audio, video, software (including games), education material, etc.
- ▶ IFPI
- ▶ Global digital revenues by industry (2008)

Games	35%
Recorded Music	20%
Newspapers	4%
Films	4%
Magazines	1%

- ▶ Digital music: €3 billion in trade value

GTA IV – 1000 developers for 3.5 years
 Estimate production cost: €80 million

▶ 11

Software Piracy

- ▶ Illegal copy and distribution of software
- ▶ Business Software Alliance (BSA) (2006)

Belgium: 27% pirate SW
 - 35% word-wide
 - 82% in China

▶ 12

Traditional Assessment of Security

- ▶ Model of the active adversary:
 - ▶ Interaction with key-instantiated oracles
 - ▶ Security Notion: objective and capabilities

▶ 13

Example security notion: **KR-CPA**

- ▶ Key Recovery under Chosen Plaintext Attack

▶ 14

Our main research question

How can cryptographic primitives be implemented in software, such that they remain secure?

▶ 15

Our Contributions

- ▶ Practical implementations (Chapter 3)
 - ▶ Cryptanalysis of white-box DES implementations
 - ▶ Analysis of basic building blocks and invertibility issue
- ▶ Formal model (Chapter 4)
 - ▶ Formalizing white-box cryptography
 - ▶ Positive and negative results
 - ▶ Extensions towards probabilistic primitives
- ▶ Applications (Chapter 5)
 - ▶ Links with diverse related techniques
 - ▶ Development of practical solutions in software security

▶ 16

Overview

- ▶ Introduction
- ▶ White-box security assessment
 - ▶ White-box implementations (Chapter 3)
 - ▶ Formal model and (im)possibility result (Chapter 4)
- ▶ Applications and related research domains (Chapter 5)
- ▶ Conclusions and future work

▶ 17

Overview

- ▶ Introduction
- ▶ White-box security assessment
 - ▶ **White-box implementations**
 - ▶ Formal model and (im)possibility result
- ▶ Applications and related research domains
- ▶ Conclusions and future work

▶ 18

White-Box Implementations

- ▶ The single line of defense is HOW to implement a cipher.
 - ▶ Software implementation with instantiated secret key

- ▶ Goal: Effort of analysis \geq BB attack
- ▶ Ideal: Implement the cipher as one big lookup table

▶ 19

Obfuscation Strategy

- ▶ S. Chow, P. Eisen, H. Johnson, and P.C. van Oorschot, 2002 [42,43]
Implement a block cipher as a network of randomized lookup tables

- ▶ Idea:
 - ▶ Spread key information on the entire network
 - ▶ Make every building block seemingly independent from the key.
- ▶ Objective: force an adversary to analyze the complete network in order to obtain secret key information \rightarrow force to resort to black-box attacks.
- ▶ Techniques: partial evaluation, by-pass encoding, matrix decomposition, etc.

▶ 20

Internal encodings

- ▶ Consider the chain $L_3 \circ L_2 \circ L_1$
- ▶ L_2 contains key information
- ▶ Obfuscate L_2 with the bijections b_1 , and b_2
- ▶ Encoded chain: $L'_3 \circ L'_2 \circ L'_1$

$$\begin{cases} L_1 \rightarrow L'_1 = b_1 \circ L_1 \\ L_2 \rightarrow L'_2 = b_2 \circ L_2 \circ b_1^{-1} \\ L_3 \rightarrow L'_3 = L_3 \circ b_2^{-1} \end{cases}$$

▶ 21

Security of encoded networks

- ▶ Local security
 - ▶ If $L_2 = f_k$ is bijective, then L'_2 is locally secure, because $\forall k, \exists b_1, b_2$ such that $L'_2 = b_1^{-1} \circ f_k \circ b_2$
 - ▶ This is infeasible to map to entire implementation (Lynn et al., 2004 [118])
- ▶ Global Security?
 - ▶ Metrics
 - ▶ Diversity $k \Rightarrow \#L'$
 - ▶ Ambiguity $L' \Rightarrow \#k$
 - ▶ Scrutiny \rightarrow Chapter 3
 - ▶ Prove \rightarrow Chapter 4

$$\begin{cases} L_1 \rightarrow L'_1 = b_1 \circ L_1 \\ L_2 \rightarrow L'_2 = b_2 \circ L_2 \circ b_1^{-1} \\ L_3 \rightarrow L'_3 = L_3 \circ b_2^{-1} \end{cases}$$

▶ 22

State of the art

▶ 23

Differential cryptanalysis

- ▶ Introduce a difference (targeted fault) in the application
- ▶ Observe the fault propagation
- ▶ Learn.

- ▶ Deployed to analyze white-box implementations at the 'edges' of the implementation (first/last round)
- ▶ In this dissertation: a new strategy of truncated differential cryptanalysis on the internal rounds (hence independent from external protections)

▶ 24

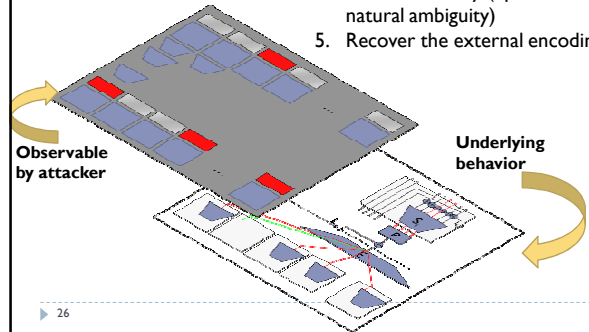

Cryptanalysis of White-Box DES Impl.

- ▶ Wyseur et al., 2007 [191]
- ▶ Cryptanalysis on internal round structure, independent of external encodings
- ▶ Strategy:
 1. Distinguish round input differences that propagate slow
 2. Construct set of differences that correspond to flips of single bits at input of DES S-boxes
 3. ...

▶ 25

Cryptanalysis of WBDES (2) (Wyseur et al., 2007 [191])

3. Compute inputs to the S-boxes
4. Recover the key (up to some natural ambiguity)
5. Recover the external encodings

▶ 26

Algebraic Cryptanalysis

- ▶ Main strategy:
 - ▶ Remove the non-linear component of the internal encodings
- Theorem 1 (O. Billet, H. Gilbert and C. Ech-Chatbi, 2004 [20]):
- $$S = \{Q \circ \oplus_{\beta} \circ Q^{-1}\}_{\beta \in GF(2^8)} \text{ yields } \tilde{Q}, \text{ with } A = \tilde{Q} \circ Q \text{ affine}$$
- ▶ Construct algebraic equations
 - ▶ Solve the equations to obtain key information.

▶ 27

Algebraic cryptanalysis

- ▶ Demonstrated on white-box AES implementation (O. Billet, H. Gilbert and C. Ech-Chatbi, 2004 [20])
- ▶ Extended to 'SLT' ciphers (includes MDS-based ciphers) (W. Michiels, P. Gorissen and H. Hollmann, 2008 [135])
- ▶ ... towards analysis of block cipher building blocks (our contribution)
 - ▶ Example: encoded addition operation

▶ 28

Analysis of basic building block

$$\begin{cases} y_0 := g \circ \oplus_{f_0^{-1}(c_0)} \circ f_1^{-1} \\ y_1 := g \circ \oplus_{f_0^{-1}(c_1)} \circ f_1^{-1} \end{cases}$$

- ▶ Hence: $y_1 \circ y_0^{-1} = g \circ \oplus_{f_0^{-1}(c_1) \oplus f_0^{-1}(c_0)} \circ g^{-1}$
- ▶ The family of functions $\{g \circ \oplus_c \circ g^{-1}\}_{c \in GF(2^4)}$ yields information on the encoding g .
- ▶ The obtained information can be used as an alternative approach to cryptanalysis the DES and AES implementations.

▶ 29

Invertibility (PR-CPA)

- ▶ wbAES: 2^{32} – because lookup tables work on per-column basis
- ▶ wbDES: 2^{96} ($\gg 2^{56}$, DES natural resistance)
 - ▶ Because of the use of parallel, encoded addition networks of 96 bits to 4 bits
 - ▶ But, XOR building block analysis defeats non-linearity of these networks
- ▶ KR-CPA is often not satisfactory
- ▶ PR-CPA (plaintext recovery under chosen plaintext attack) is much more interesting in practice

▶ 30

Conclusions chapter 3

- ▶ White-box implementations of DES and AES are insecure
 - ▶ Differential cryptanalysis
 - ▶ Algebraic cryptanalysis
- ▶ Attacks are specific to the cryptographic primitive, or a building block that is present.
 - ▶ Towards a block cipher with building blocks that is suitable to be implemented in software
 - ▶ Proposals are formulated in dissertation.
- ▶ Extensions towards non-invertibility and key update

▶ 31

Overview

- ▶ Introduction
- ▶ White-box security assessment
 - ▶ White-box implementations
 - ▶ Formal model and (im)possibility result
- ▶ Applications and related research domains
- ▶ Conclusions and future work

▶ 32

Formal approach to WBC

- ▶ Objectives
 - ▶ Formalize white-box cryptography
 - ▶ Capture the security of white-box solutions (beyond scrutiny)
 - ▶ What is feasible?
 - ▶ Negative results
 - ▶ Positive results
- ▶ Related
 - ▶ Theoretical models for Obfuscation
 - Obfuscation – hide characteristics of a program P (program code, internal data values, sensitive routines, etc.)
 - O is an obfuscator, O(P) functionally equivalent obfuscated program.

▶ 33

Obfuscation – soundness

- ▶ Predicate-based definition (Barak et al., 2001 [6])

$$\left| \Pr[A(O(P)) = \pi(P)] - \Pr[S_A^P(1^{|P|}) = \pi(P)] \right| \leq \text{neg}(|P|)$$

- ▶ Distinguisher-based definition

$$\left| \Pr[D(A(O(P))) = 1] - \Pr[D(S^P(1^{|P|})) = 1] \right| \leq \text{neg}(|P|)$$

▶ 34

Models for Obfuscation

- ▶ Many models and results have been presented, but...
 - ▶ Predicate-based definition is too weak (meaningless)
 - ▶ Distinguisher-based definition is too strong (nothing interesting possible: deterministic & obfuscatable → learnable)
- ▶ Learnable
 - ▶ Learnable functions not of our interest
 - ▶ Cryptographic scheme's should be non-learnable.
- ▶ Also, obfuscation cannot capture cryptographic security requirements

▶ 35

Our approach to capture WBC

- ▶ A new model, based on predicate-based notion for obfuscation, specific to WBC

(Saxena and Wyseur, 2008 [165])

- ▶ We capture “meaning” with security notions
 - ▶ Attack goals
 - ▶ Attack capabilities (described as a game between a challenger and the adversary)

“White-Box Property”

▶ 36

Our approach to capture WBC (2)

$$\begin{cases} \text{AdvBB}_A^{sn}(k) = \Pr \left[r \stackrel{R}{\leftarrow} \{0,1\}^{p_{in}(k)} : \text{GameBB}_A(1^k, sn, r) = 1 \right] \\ \text{AdvWB}_{A,O,Q}^{sn}(k) = \Pr \left[r \stackrel{R}{\leftarrow} \{0,1\}^{p_{in}(k)} : \text{GameWB}_{A,O,Q}(1^k, sn, r) = 1 \right] \end{cases}$$

▶ O is a secure obfuscator for Q , under the sn security notion, if

$$\left| \max_{A \in \text{PPT}} \text{AdvWB}_{A,O,Q}^{sn}(k) - \max_{A \in \text{PPT}} \text{AdvBB}_A^{sn}(k) \right| \leq \text{neg}(|k|)$$

Negative results (Saxena and Wyseur, 2008 [165])

▶ For any non learnable family Q , there exist a non-obfuscatable security notion (this is stronger than Barak et al., 2001)

Proof of impossibility result

- ▶ Q is non-learnable

$$\begin{cases} q \stackrel{R}{\leftarrow} \{0,1\}^k \\ x \stackrel{R}{\leftarrow} \{0,1\}^k \\ a \stackrel{R}{\leftarrow} \{0,1\}^{P_Q(k)} \end{cases}$$
- ▶ Win: if $(s=x)$ and 'not more than one query to Q_1 '
- ▶ BB adversary – how to find x ?
 - ▶ Guess x – prob: 2^{-k}
 - ▶ Guess a – prob: $2^{-P(k)}$
 - ▶ Guess q – prob: 2^{-k}
 - ▶ Luck

▶ $Q_1[q_1]$ (input Y) {
If $(Y(a) = Q[q](a))$ then
output x
else output 0 }

Black-box advantage: $\forall A \in \text{PPT} : 0 \leq \text{AdvBB}_A^{\text{guess-x}}(k) < \alpha(k)$

Proof of impossibility result (2)

- ▶ Q is non-learnable

$$\begin{cases} q \stackrel{R}{\leftarrow} \{0,1\}^k \\ x \stackrel{R}{\leftarrow} \{0,1\}^k \\ a \stackrel{R}{\leftarrow} \{0,1\}^{P_Q(k)} \end{cases}$$
- ▶ Win: if $(s=x)$ and 'not more than one query to Q_1 '
- ▶ WB adversary – how to find x ?
 - ▶ Use the code $O(Q[q])$ as Y

▶ $Q_1[q_1]$ (input Y) {
If $(Y(a) = Q[q](a))$ then
output x
else output 0 }

White-box advantage: $\exists A \in \text{PPT} : 1 \geq \text{AdvWB}_{A,O,Q}^{\text{guess-x}}(k) \geq 1 - \beta(k)$

Proof of impossibility result (3)

- ▶ Black-box adversary:

$$\forall A \in \text{PPT} : 0 \leq \text{AdvBB}_A^{\text{guess-x}}(k) < \alpha(k)$$
- ▶ White-box adversary:

$$\exists A \in \text{PPT} : 1 \geq \text{AdvWB}_{A,O,Q}^{\text{guess-x}}(k) \geq 1 - \beta(k)$$
- ▶ White-box property: O is secure for Q under sn , if:

$$\left| \max_{A \in \text{PPT}} \text{AdvWB}_{A,O,Q}^{sn}(k) - \max_{A \in \text{PPT}} \text{AdvBB}_A^{sn}(k) \right| \leq \text{neg}(|k|)$$

▶ But:

$$\left| \max_{A \in \text{PPT}} \text{AdvWB}_{A,O,Q}^{sn}(k) - \max_{A \in \text{PPT}} \text{AdvBB}_A^{sn}(k) \right| > 1 - \alpha(k) - \beta(k)$$

Positive result (Saxena and Wyseur, 2008 [165])

- ▶ There exists an obfuscator O that turns a IND-CPA secure, symmetric encryption scheme into an IND-CPA secure asymmetric encryption scheme
- ▶ Based on the bi-linear Diffie-Hellman assumption

▶ Remark: positive result is based on a cipher that consists of asymmetric building blocks (pairings). We started with white-box crypto for symmetric encryption schemes (DES, AES).

Overview

- ▶ Introduction
- ▶ White-box security assessment
 - ▶ White-box implementations
 - ▶ Formal model and (im)possibility result
- ▶ Applications and related research domains
- ▶ Conclusions and future work

▶ 43

Applications

- ▶ Application domains
 - ▶ New and improved cryptographic primitives
 - ▶ Enforce (with) hardware
 - ▶ Computing in the encrypted domain
 - ▶ Software protection
 - ▶ Case study
 - ▶ Digital Rights Management
- Related techniques**
- Asymmetric cryptography
 - (Programmable) random oracle model
 - Improve side-channel protection techniques
 - Homomorphic encryption
 - Secure function evaluation (Yao's garbled circuits)
 - Software tamper resistance
 - Software diversity
 - Trustworthy execution (TC, remote entrusting, VBRPE)
 - Traitor tracing

▶ 44

Software security

- ▶ White-box cryptography is only a small piece in the puzzle.
 - ▶ 128-bit AES key → 770 Kbytes key (the white-box AES implementation lookup tables)
 - ▶ Now we got a larger key... so what?
 - ▶ Result is more flexible
 - ▶ Fix key into the application (prevent *code lifting*) – external encodings
 - ▶ A leverage for other software protection techniques
 - Traitor tracing
 - Obfuscation
 - Software Tamper Resistance
 - ...

▶ 45

Overview

- ▶ Introduction
- ▶ White-box security assessment
 - ▶ White-box implementations (Chapter 3)
 - ▶ Formal model and (im)possibility result (Chapter 4)
- ▶ Applications and related research domains (Chapter 5)
- ▶ Conclusions and future work

▶ 46

Conclusions and Future Research

- ▶ White-Box Implementations
 - ▶ State of the art implements shown to be insecure
 - ▶ Analysis of basic building blocks (lead to alternative attacks and defeat of PR-CPA security)
 - ▶ Future work: towards new block ciphers and design principles
- ▶ Theoretic model for White-Box Cryptography
 - ▶ A formal model has been introduced – context captured by security notions
 - ▶ Positive and negative results have been presented
 - ▶ A provably IND-CPA secure white-box implementation
 - ▶ Future work: prove other constructions – extensions towards probabilistic functions
- ▶ Applications
 - ▶ Use of WBC in practice, and relation with other research fields
 - ▶ Future work: investigate new directions, inspired by other fields
